The **Cell Division** feature transforms layers into fluid, interconnected shapes using liquid metaball deformation, blending layers and softening corners for a seamless appearance. In "Normal" mode, this creates adhesion between multiple layers and removes sharp edges. "Bubble Mode" allows shapes to resemble transparent bubbles, which can be customized. The "Layers" mode further enhances adhesion and smooths corners, while the "Contents" mode focuses on fixing adhesion within the internal shapes of a layer without altering its edges.
